Plan Now to Attend the MU Pest Management Field Day on July 14th

By Kevin Bradley

The annual Pest Management Field Day will be held this July 14th at the Bradford Research and Extension Center near Columbia, Missouri. As in recent years, we have expanded the focus of this field day to include a variety of pest management topics that are of interest to agricultural industry representatives, agrichemical dealers, Extension specialists, and producers throughout Missouri and surrounding states.

Registration will begin at 8:30 a.m. and will include guided wagon tours with stops that feature presentation of results and talks by university weed scientists, entomologists, plant pathologists, and agronomists. There will be a $10 registration fee collected at the time of check-in. This will cover costs associated with lunch and will provide each attendee with a tour booklet that describes the layout and location of each experiment.

Some of the weed management research topics and trials that will be discussed at this year’s field day include: options for volunteer corn control in corn and soybeans, a preview of new herbicides and herbicide programs that will be available in 2011 and beyond, considerations for future herbicide-resistant crop offerings, influence of weed removal on cattle grazing preference in Missouri pastures, control of waterhemp and Palmer amaranth in conventional, LibertyLink, or Roundup Ready soybean systems, and finally an update on the status and control recommendations for glyphosate-resistant weeds in Missouri.

Dr. Bruce Hibbard, USDA-ARS entomologist, will be discussing the latest research results and future options pertaining to the control of corn rootworm in Missouri. Dr. Wayne Bailey, state extension entomologist, will also be discussing the changes in insect population dynamics that have occurred in soybeans over the past several seasons and how we should be adapting to these changes.

Dr. Laura Sweets, state extension plant pathologist, will discuss results from a multi-state trial evaluating the effects of different sources of soybean cyst nematode resistance on field population levels of SCN. Additionally, Dr. Sweets will discuss corn and soybean seed treatments and an update on the status of soybean rust in the U.S.

As usual, after lunch attendees will have the opportunity to view plots that showcase a wide variety of herbicide treatments and weed management systems for use in corn, soybean, or grain sorghum on their own. This year we have more than 50 trials and 700 separate weed management treatments on display at the research and extension center.

For certified crop advisors, 2 CEU credits for the field day are pending. If you plan on attending the field day, you must pre-register before July 10th by calling 573-884-7945 or by sending an e-mail to chismt@missouri.edu. The Bradford Research and Extension Center is located 7 miles east of Columbia, off of highway WW. For more complete directions call 573-884-7945 or visit http://aes.missouri.edu/bradford/index.stm.

Double Crop Soybean Needs Tender Loving Care for Best Yields

By Allen Wrather

I was recently listening to some old men talk about stuff that old men talk about. I understand that you may think me mentally off for sitting around listening to old men, but I find it easier to do now that I have become one of these old men. As usual, the first story told by an old man never has a chance because other old men will tell stories to top the first. The best story this particular day was about the freeze on Mother’s Day one year that killed all the crops and was so severe the radiators in some tractors froze and broke. There of course were some doubts among the other old men about the validity of this story. Most old men can’t agree on much. However, these old men were farmers and they all agreed that soybean will yield best when grown on well drained, fertile soil; when the weather is mild (72° nights and 90° days); when sunshine is abundant; and when it rains 1.5 inches every Friday afternoon. All of these old farmers agreed that these conditions usually only develop in their dreams. The conditions that typically occur are too much or too little rain, poor drainage, too little fertilizer, temperatures too high or low, and too much clay soil. These more typical conditions can make soybean farming difficult but not impossible, and soybean can grow and yield well in these conditions with tender loving care (TLC). Tender loving care will be especially beneficial to double crop soybean. Wheat harvest will begin in south Missouri has started and will begin in north Missouri very soon, and farmers will begin to plant soybean in some of these fields. I have some suggestions for these farmers to help the double crop soybean crop grow and yield as well as possible.

1. For south Missouri, plant a maturity group (MG) 4 or early 5 variety. In our tests, yields of mid-June planted MG 3 varieties were always lower than yield for MG 4 and 5 varieties. The yields for the MG 4 and 5 varieties were about the same. The harvest date for a mid-June planted MG 4 variety will be about mid-October.
2. Plant seed that has been commercially treated with a fungicide in fields where irrigation will be used to help the soybean seed germinate. This treatment will help protect the seeds and seedlings from rot that may develop due to wet soil from irrigation. Fungicide seed treatments available now are more effective that those available a few years ago.
3. Scout the crop frequently during the summer and fall to determine if insecticides are needed, especially for stink bugs and pod feeders; to determine if foliar fertilizer is needed, especially potassium; and to determine if a foliar fungicide is needed. Double crop soybean that may yield 40 bushels per acre or more may benefit from a foliar application of fungicides such as Quadris, Headline, Stratego, or Quilt.
4. Pay attention to news reports, especially beginning in August, about soybean rust development. Rust is probably a greater threat to our double crop than full season soybean.
5. Irrigate properly.

Following these suggested procedures will give farmers a better chance of realizing a profit with double-crop soybean in 2010.

Early Season Soybean Diseases

By Laura Sweets

This could be another interesting year for early season soybean diseases in Missouri. Because of the erratic weather patterns, soybean planting is behind average in some regions of the state. Since a significant number of acres were just planted during the last week to 10 days, plants in those fields are just emerging. The next several weeks will be the test for how severe early season seed decay, damping off and seedling blight are in soybeans this year. However, the unusual fluctuations in both soil moisture and soil temperatures could increase the potential for Pythium seed decay and seedling blight as well as Phytophthora seedling blight. The early season soybean diseases include those that cause seed decay, seedling blights and root rots of soybean. Most of these early season soybean diseases are caused by fungi in the soil that are found wherever soybeans are grown. *Pythium*, *Phytophthora*, *Rhizoctonia* and *Fusarium* are the most common of these early season pathogens, although *Macrophomina* (charcoal rot fungus) may also cause early season seedling problems.

Soybean seedling blights have the potential to cause losses in Missouri soybean fields every year. The specific seedling blights that occur and their severity vary with the environmental conditions each season. With the changes in weather patterns this spring and soybean planting delayed in much of the state because of wet soil conditions, it is difficult to predict which, if any, seedling blights may occur or may cause significant problems this season.

*Pythium* and *Phytophthora* are favored by wet conditions and are more likely to be serious problems when wet conditions exist at or just after planting. *Rhizoctonia* and *Fusarium* are not as restricted by soil moistures and soil temperatures but still need some moisture to initiate infection. *Macrophomina phaseolina* grows best at temperatures between 82-95°F. Infection of seedlings with *Macrophomina* is most likely to occur if conditions

---

Continued on page 85
of high soil temperatures and low soil moisture exist during the first two to three weeks after planting.

Symptoms of *Pythium damping-off* range from seed rot or preemergence damping-off to early postemergence damping-off. Affected tissue develops a soft, watery brown rot. Pythium damping-off is most likely to occur in cool (50-55°F), wet soils.

*Phytophthora* can cause seed rot, preemergence damping-off and early postemergence damping-off. Initially affected tissue develops a soft, watery brown rot. Within several days the affected plant parts may dry out and shrivel up becoming dark, dry and brittle. This early stage Phytophthora is difficult to distinguish from *Pythium* damping-off. Phytophthora can also cause a seedling blight in which established seedlings turn yellow, wilt and die. Generally the entire seedling is affected and roots may be poorly developed and rotted. Phytophthora root rot is more likely to occur in heavy, wet soils, low areas or compacted areas, but it may occur in light soils or better drained areas if heavy rains occur after planting.

*Rhizoctonia* can cause seedling blight and root rot of soybean. Affected stands may have an uneven appearance and seedlings appear pale green in color and stunted in growth. The identifying feature of this disease is a small, reddish lesion on one side of the stem at or just below the soil line. This lesion develops into a sunken, cankered area at the point of infection. Sometimes the lesion will expand to completely girdle the stem. On severely infected seedlings, the entire hypocotyl may be discolored and shriveled into a dry, stringy or wiry stem.

*Fusarium* can also cause root rot of soybean. Infection is usually confined to roots and lower stems. The lower part of the taproot and the lateral root system may be discolored, deteriorated or completely destroyed. General roots show a nondescript brown discoloration and a dry, shrunken rot. Above ground portions of plants may appear off-color and stunted. Plants with severe *Fusarium* root rot may die prematurely.

Charcoal rot, caused by *Macrophomina phaseolina*, may be more commonly recognized as a mid to late season disease on maturing soybean plants, but it can also occur early in the season on seedlings. Infected seedlings tend to show a reddish brown discoloration from the soil line up the stem. The discolored area changes from reddish brown to dark brown to black. Foliage may appear off color or begin to dry out and turn brown. If the growing point is killed, a twin stem plant may develop. Under hot, dry conditions, infected seedlings may die. Under cooler, wetter conditions, infected seedlings may survive but carry a latent infection. Then symptoms may reappear later in the season with hot, dry weather.

Once the crop has been planted, there is little that can be done to reduce incidence or severity of soybean seedling diseases. Additional stress from poor growing conditions, herbicide injury or other factors may compound problems with soybean seedling diseases. Prior to planting it is important to consider variety selection (especially in fields with a history of *Phytophthora*), fungicide seed treatment, crop rotation, seedbed preparation and conditions at planting.
following spring larvae quickly finish development, pupate, and emerge as adult beetles beginning in early June in most years.

Japanese beetle adults often congregate in large numbers to feed on foliage and fruit of over 400 different host plants worldwide (approximately 220 in US). Hosts include a wide variety of ornamental, tree, small fruit, and field crop plants. Typical feeding damage by the beetles is often seen as a lace-like pattern on host plant foliage as beetles avoid leaf veins when feeding. Beetles often begin feeding on the top of plants and move downward. They tend to select plants which emit strong odors and often feed in large groups on host plants. Tassels and silks of corn can be severely damaged by adult feeding, whereas foliage feeding is common on soybean. Feeding on corn silks can disrupt pollination and result in substantial yield losses. Foliage feeding on soybean is less damaging, although small double-crop soybean may sustain economic damage. The grub stage of this pest will feed on plant roots of both corn and soybean with most feeding occurring in late June, July and August. Damage to plant root hairs may result in poor uptake of water and nutrients or be more severe and cause reduced stands through plant mortality.

In field corn, an insecticidal treatment is justified if during the silking period there are an average of 3 or more beetles present per ear, silks have been clipped to 1/2 inch or less in length, and pollination is less than 50% complete. For soybean, treatment is justified if foliage feeding exceeds 30% prior to bloom and 20% from bloom through pod fill. The following insecticides are recommended for control of Japanese Beetle in field corn and soybean in Missouri.

### Table 1. Insecticides Recommended for Control of Japanese Beetle Adults in Field Corn

**Economic Threshold:** Treat when 3 or more beetles are present on silks before pollination is less than 50% complete and silks are chewed to 1/2 inch or less in length.
